

# Modal Workflow

## 1 OVERVIEW

---

Modal workflow is impossible with any other web development framework. It's usually emulated using a combination of client side callbacks and ajax requests. Wisej supports full modal workflow and nested modal at any (configurable) level. The resulting code is much simpler, consistent and manageable.

## 2 WHAT TO LOOK FOR

---

- The code flow is sequential: the next line is executed only after the message box is closed.
- The code is stateful: you can access the modal dialog data when closed.
- The code is simpler: imagine having to ask the user on a remote browser what do after he or she clicked [Submit] and you are processing a web request.
- HelpTip extender used to show additional help tips in relation to the active control.

## 3 HOW TO CREATE YOUR OWN

---

You can open any window (Wisej.Web.Form) as a modal dialog like this (the using pattern is just good practice):

```
using (Dialog1 dialog = new Dialog1()) {  
    if (w.ShowDialog() == DialogResult.OK) {  
        ...  
    } else {  
        ...  
    }  
}
```

Or you can use the MessageBox class to show quick and easy modal message boxes.
